Angi JSON Lead Feed

Angi provides a simple JSON mechanism for delivering customer leads to a partner endpoint. The leads will be delivered in real-time when a lead is assigned to your account.

Partner Requirements

Testing Endpoint URL:

Please define the secure URL you would like us to post the leads to for testing integration.

Production Endpoint URL:

Please define the secure URL you would like us to post live leads to once the process has been tested.

Authentication:

During initial setup, we will request contact information for a person who can provide us with your API key. We will coordinate a phone call in order to receive the API key securely.

Once the integration is set up, we will send API key via HTTP Request Header, i.e. X-API-KEY: [CLIENT_API_KEY_PROVIDED].

Handling the Response:

Once we post to your URL, we expect an HTTP Response code "200" back with a message in the body of the response indicating the success or failure of a particular post. Anything other than a success message or a 200 will result in a retry.

Success string:

Please define a word pattern/string that we can search for indicating that the posting was a success. This can be anything you like, and the contents of the response will be stored, so any unique job numbers or other points of data that can be cross referenced are preferred. As an example, a quasi XML response like: <success>job number 12345</success> is suitable.

Errors/Retry:

In the event that we experience an error we will retry the lead 3 times with a 15-minute interval in between retries. Please ensure that these retries do not create duplicate content issues with your system.

Errors include:

- a response code other than 200
- a server time-out
- a 200 with content that doesn't match the "success string"

If the lead does not send after the third try, we will notify you via email. Please provide the email address or addresses you would like to receive failure notifications.
